3 PhD in Molecular Biology and Genetic Engineering. Hospital Universitario “Dr. José Eleuterio González” / Universidad Autónoma de Nuevo León, Monterrey, México.
4 MD. Facultad de Medicina/Hospital Universitario “Dr. José Eleuterio González”/Universidad Autónoma de Nuevo León, Monterrey, México.
5 PhD, MSc. N, Degree in Nutrition. Consulta No. 2 Nutrición/Hospital Universitario “Dr. José Eleuterio González” /Universidad Autónoma de Nuevo León, Monterrey, México.

**INTRODUCTION:** Metabolic syndrome (MS), a combination of diabetes, high blood pressure and obesity, is a well-known risk factor for developing non-alcoholic fatty liver disease, condition that can lead to serious liver damage such as liver fibrosis (LF), which is characterized by excessive deposition of connective tissue, progressing to cirrhosis and hepatocellular carcinoma. Nevertheless, subjects without MS may also develop LF. Non-invasive LF predictors based upon anthropometric and biochemical data have been reported. **AIM:** To compare anthropometric, genetic, and biochemical parameters in subjects with or without MS, and at risk for developing liver fibrosis. **METHODS:** A randomized sample of 200 individuals was taken from the 2015 Nuevo León State Health Survey. Inclusion criteria were age ≥18 and a previously stored blood sample. According to the parameters obtained, subjects were classified as either with or without MS and their NAFLD fibrosis score was calculated considering variables such as age, BMI, glycemia, albumin, platelets, and AST/ALT ratio, to establish a high or low risk of LF. Comparisons of weight, age, BMI, blood glucose, total cholesterol, triglycerides, platelets, albumin, AST/ALT ratio, and HDL were made between groups. DNA was extracted from stored blood samples and genotyped, using q-PCR, according to variants in four genes related to: fatty acid (FA) metabolism (PNPLA3, rs738409), adipocyte differentiation (PLIN2, rs35568725), glucose metabolism (GCKR, rs1260326 and rs780094), and BMI (UCP2, rs659366). Statistical analysis was performed with SPSS v.22. A p value <0.05 was taken as level of significance. **RESULTS:** A total of 134 subjects were included and divided into four groups (n): With MS+ high risk (35), With MS+ low risk (34), Without MS+ high risk (32), Without MS+ low risk (33).

**Table:** Significant Main Risk Factors for Developing Liver Fibrosis in Subjects with and without Metabolic Syndrome.

**Key words:** Fibrosis; Hispanic; Genetics. (Source: MeSH-NLM).
