#### 1 ABSTRACT

#### 2 Background

- 3 This systematic review aimed to assess the relationship between blood pressure variability, cognitive function,
- 4 and the potential for dementia in individuals with hypertension. Hypertension has been increasingly
- 5 associated with cognitive impairment, with studies suggesting it may lead to structural and functional changes
- 6 in the brain. This association involves damage to the blood-brain barrier, white matter lesions, and
- 7 microvascular abnormalities, highlighting the importance of managing blood pressure to preserve cognitive
- 8 health."

#### 9 Methods

- 10 The review adhered strictly to the Preferred Reporting Items for Systematic Reviews and Meta-analyses
- 11 (PRISMA) guidelines. A comprehensive search was conducted in databases, including PubMed, Research
- 12 Gate, Google Scholar, and Science Direct. The inclusion criteria required studies that examined the
- association between blood pressure variability and the occurrence or progression of dementia and cognitive
- 14 impairment. Two independent reviewers evaluated each study's quality and potential bias using study-specific
- 15 tools before inclusion.

#### 16 Results

- 17 There were 17 studies, including four systematic reviews and meta-analyses, four randomized controlled
- trials, and nine observational studies, with 16,985,492 participants. The findings indicated that late-life blood
- 19 pressure had a stronger association with cognitive function than midlife blood pressure. Hypertension was
- 20 linked to an increased risk of all-cause dementia, Alzheimer's disease, and vascular dementia. Anti-
- 21 hypertensive medications could reduce the risk of dementia or cognitive impairment, although the specific
- type of medication did not significantly affect overall cognitive performance. A significant limitation of this
- 23 review was the heterogeneity in diagnostic criteria, cognitive assessment tools, and imaging techniques used
- among the studies, which limited direct comparisons and conclusive findings.
- 25 Conclusion
- 26 Blood pressure variability emerged as a potential predictor for cognitive impairment. Implementing strategies
- to reduce blood pressure variability may help mitigate the risk of dementia and improve cognitive outcomes in
- 28 vulnerable populations.

3 this number is projected to increase thrice by 2050. Dementia affects the economy with global costs estimated 4 at United State \$1 trillion annually. According to the 2017 Lancet Commission on dementia prevention, 5 intervention, and care, the nine potentially modifiable risk factors for dementia include less education, 6 hypertension, hearing impairment, smoking, obesity, depression, physical inactivity, diabetes, and low social 7 contact. The 2020 report of the Lancet Commission included three more risk factors for dementia: excessive 8 alcohol consumption, traumatic brain injury, and air pollution. Together the 12 modifiable risk factors account 9 for around 40% of worldwide dementias, which consequently could theoretically be prevented or delayed.<sup>1</sup> 10 11 Hypertension is a leading cause of age-related cognitive impairment. Hypertension was previously associated 12 primarily with vascular dementia but has recently been linked to Alzheimer's disease as well.<sup>2</sup> It is wellestablished that midlife (40-65years age) hypertension is a modifiable risk factor for late-life dementia (>65

The number of older people with dementia is rising. Worldwide, dementia affects around 50 million people and

- 13 14
- years if age).<sup>3</sup> One meta-analysis found that blood pressure lowering with antihypertensive agents was significantly associated with a lower risk of dementia or cognitive impairment.<sup>4</sup> Another study concluded that 15
- 16 visit-to-visit blood pressure variability (BPV) independent of average blood pressure is associated with higher
- cardiovascular risk in older adults and that older subjects with higher levels of blood pressure variability have 17
- 18 worse cognitive function.<sup>5</sup> Mechanisms by which high Systolic Blood Pressure (SBP) and BPV are thought to
- 19 contribute to cognitive impairment include endothelial dysfunction, microemboli, and oxidative stress,
- 20 promoting cerebral atherosclerosis.<sup>6</sup> Another study found that a large variation in blood pressure, rather than
- 21 the direction of the variation, increases the risk of dementia.<sup>7</sup> Another study added that having both higher
- 22 Systolic Blood Pressure Variability (SBPV) and Diastolic Blood Pressure Variability (DBPV) additively
- 23 increased the risk of dementia and its subtypes in a general population.8
- 24

25 Multiple studies have been carried out to find the exact association between hypertension, BPV, and cognitive

26 impairment. However, we still don't know the exact mechanisms through which hypertension and BPV lead to

- 27 cognitive impairment and ultimately to dementia. If we do find the mechanisms responsible, it would help us
- 28 further to prevent dementia in later stages of life. Moreover, the role of anti-hypertensives in the prevention of
- 29 dementia is unclear. This review aims to further explore the correlation between high blood pressure, blood
- 30 pressure variability, and cognitive impairment, and to examine the role of antihypertensives in preventing
- 31 cognitive impairment.

34 dementia and cognitive impairment. Firstly, the age and gender composition of participants in these studies 35 contribute to our understanding of the relationships between blood pressure, cognitive function, and the risk of 36 dementia. Secondly, the findings regarding the association between blood pressure variability and the 37 occurrence or progression of dementia and cognitive impairment. Thirdly, the diverse diagnostic and testing

This systematic review addresses several key questions regarding the association between hypertension,

- 38 methods employed in these studies contribute to our understanding of the impact of blood pressure on
- 39 cognitive function and the risk of dementia. Furthermore, the effects of anti-hypertensive medications on the
- 40 development and progression of dementia and cognitive impairment. Additionally, the prognostic value of
- 41 SBPV or DBPV for cognitive impairment and the risk of dementia. Lastly, long-term SBPVs and mean heart

- 1 rate levels affect cognitive function in high-risk individuals. This systematic review assesses the correlation
- 2 between BPV and dementia, particularly the role of hypertension in cognitive impairment, stratified by age and
- 3 gender, while examining the effects of anti-hypertensive treatment. Despite existing research, the precise
- 4 mechanisms connecting BPV to cognitive decline remain underexplored, necessitating a systematic review to
- 5 better elucidate these associations and potential therapeutic implications.
- 6

#### 7 METHODS

- 8 This systematic review followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses
- 9 (PRISMA) 2020 guidelines.<sup>9</sup>

#### 10 Search Strategy

- 11 A comprehensive literature search was performed using PubMed, ResearchGate, Google Scholar, and
- 12 ScienceDirect databases. The following filters were applied while considering the studies for the identification
- 13 process for the review: Studies in the English language, free full-text, and Human studies. Keywords and
- 14 Medical Subject Headings (MeSH) terms were used to identify 12 studies about our discussion. The search
- 15 was generated using keywords such as "anti-hypertensives," "dementia," "hypertension," "Alzheimer's
- disease," "cerebrovascular disease/stroke," "neurovascular dysfunction," and combining them using the
- 17 BOOLEANs "AND" and "OR." *Table 1* summarizes the search strategy used for the identification process in
- this systematic review. The search strategy for this review concluded in November 2023.
- 19 Eligibility criteria for considering studies under this review

#### 20 Inclusion criteria

- 21 The studies were chosen for inclusion based on the following participant, intervention, and outcome
- 22 characteristics. Population: Adults without specific medical conditions, diagnosed with or at risk for
- 23 hypertension, Intervention: Blood pressure variability, Comparison: Consistent blood pressure levels or low
- blood pressure variability, Outcome: Association between blood pressure variability and the occurrence or
- 25 progression of dementia and cognitive impairment.
- 26 The following study characteristics were considered for inclusion: studies written and published in the English
- 27 language, focusing on a population age over 50 years, involving only human participants, available as free full
- text, published within the last 30 years (1993-2023). The studies were required to investigate the association
- 29 between blood pressure variability and the occurrence or progression of dementia and cognitive impairment.
- 30 Diagnostic and testing methods for dementia and cognitive impairment needed to be clearly described and
- 31 appropriate cognitive assessment tools with standardized outcome measures were required. The studies were
- 32 required to have an adequate sample size and report the duration of blood pressure follow-up for cognitive
- 33 performance. Study designs including systematic reviews, meta-analyses, randomized controlled trials, and
- 34 observational studies were considered for inclusion.

#### 35 Exclusion criteria

- To ensure the relevance and quality of the included studies, certain exclusion criteria were applied: Animal
- participants, studies published before 1993, patients aged less than 50 years, Non-English language studies,
- paid articles, Gray literature, Studies with incomplete or insufficient data, Case reports, editorials, reviews, and
- 39 conference abstracts, Studies without specific mention of blood pressure variability, Studies lacking relevant
- 40 outcomes related to dementia and cognitive impairment, Studies using cognitive assessment tools that are not
- standardized, Studies without clear diagnostic and testing methods for dementia and cognitive impairment.

- 2 By applying the above inclusion and exclusion criteria, the systematic review aims to include relevant studies
- that provide valuable insights into the association between blood pressure variability and the occurrence or
- 4 progression of dementia and cognitive impairment in adults with hypertension or at risk for hypertension.

#### 5 Selection of studies for inclusion in the review

- 6 The screening of the articles was carried out by AJ and VB, who independently reviewed the titles and
- 7 abstracts of the identified studies. Any disagreements were resolved through discussion and consensus
- 8 between the two reviewers. In cases where a consensus could not be reached, a third reviewer, AP, was
- 9 involved in providing a final decision. This ensured a thorough evaluation of all potentially relevant records
- 10 and minimized bias. Throughout the screening process, detailed notes were taken to record the specific
- 11 reasons for excluding research studies from the review.

#### 12 Assessment of the Methodological Quality and Risk of Bias

The remaining studies were individually evaluated for quality by two independent authors using study-specific techniques. Each assessment tool has its scoring system, and studies with a score of more than 70% were

- accepted for inclusion in this study. The quality assessment of the studies, as well as the tools utilized, are
- 16 summarized in *Tables 2 and 3*.<sup>10-12</sup>
- 17

#### 18 **RESULTS**

19 A systematic search yielded a total of 11,690 records from various sources, including PubMed (n=3,112),

- 20 Research Gate (n=100), Science Direct (n=8,310), and Google Scholar (n=168). After removing duplicates
- 21 (n=8,096) and conducting an initial screening based on titles and abstracts leaving 125 studies for full-text
- screening. Among these, 106 studies were excluded during full-text screening, resulting in 19 studies that
- 23 underwent quality assessment. Ultimately, two studies were excluded, leaving 17 studies with a total of
- 24 16,985,492 participants for inclusion in the systematic review.<sup>3-8, 13-23,</sup> Based on the assessment tools
- employed, the studies' quality scores exceeded 70%. Data collection concluded on December 3, 2023. For a
- visual representation of the selection process, refer to Figure 1, which presents the PRISMA flow chart
- 27 detailing the identification and screening process used to select the final articles for review.
- 28

29 The studies on hypertension and late-life dementia involved participants aged 54 to 84.4 years, with some

- 30 studies having a majority of male participants and others with more balanced gender distribution. The duration
- of blood pressure follow-up for cognitive performance and the mean blood pressure values varied across the
- 32 studies, providing valuable insights into the relationship between blood pressure and cognitive outcomes in
- different contexts. Each of these studies contributed to our understanding of the relationship between blood
- 34 pressure and cognitive function by considering different follow-up durations and mean blood pressure values
- 35 in their respective populations.
- 36
- 37 The diagnosis and testing methods employed in the studies varied, reflecting the diverse approaches to
- assessing cognitive function and dementia. Several studies relied on comprehensive neuropsychological
- 39 assessments to evaluate cognitive performance. Hughes et al, in their meta-analysis, utilized various cognitive

- 1 tests, including the Mini-Mental State Examination (MMSE), to assess cognitive impairment.<sup>4</sup> Similarly, Yano
- 2 et al employed cognitive function tests, including the Digit Symbol Substitution Test and the Word Recall Test,
- to evaluate cognitive function.<sup>18</sup> Other studies, such as Chiu et al, focused on the diagnosis of dementia as an
- 4 outcome.<sup>20</sup> These studies incorporated clinical diagnostic criteria, such as the Diagnostic and Statistical
- 5 Manual of Mental Disorders (DSM) or the International Classification of Diseases (ICD), to identify cases of
- 6 dementia. Additionally, imaging techniques, such as magnetic resonance imaging (MRI), were used to assess
- 7 structural brain changes associated with cognitive impairment.<sup>19</sup> Therefore, a comprehensive understanding of
- 8 the diagnostic and testing methodologies used is essential for accurately evaluating the impact of blood
- 9 pressure on cognitive function and dementia risk.
- 10

#### 12 Data extraction and management

13 *Table 3* includes a summary of the included studies. The data was extracted in a Microsoft Excel spreadsheet

- by MK, SSV, and Ad.P to include authors, year of publication, mean age and % sex of the patients, sample
- size, type of study, duration of blood pressure follow-up for cognitive performance, mean BP, outcomes,
- diagnosis and testing, and conclusions. The data extraction concluded on Nov 2023. We did not use any
- 17 statistical analysis to interpret results because of the heterogeneity of data and qualitatively analyzed the
- 18 included studies.
- 19

### 20 DISCUSSION

21

### 22 Hypertension and Late-life Dementia and cognitive impairment

- 23 Midlife hypertension is significantly associated with a 1.19- to 1.55-fold excess risk of cognitive disorders, with
- 24 potential benefits of a 21% reduction in dementia risk through antihypertensive medications.<sup>19</sup> Chiu et al
- indicated a higher dementia risk among the elderly subgroup, suggesting a potential association between
- 26 hypertension and late-life dementia.<sup>20</sup> Similarly, the study conducted by Ya Nan and colleagues suggests a
- 27 potential association between BPV, specifically SBPV or DBPV, and the risk of developing all-cause dementia
- in later life.<sup>24</sup> The research findings indicate that fluctuations in blood pressure may be linked to an increased
- 29 likelihood of developing dementia.<sup>13</sup> Xu et al found that late-life blood pressure had stronger associations with
- 30 cognitive function than mid-life blood pressure.<sup>21</sup> Furthermore, among late-life blood pressure control groups,
- those with controlled hypertension had higher cognitive scores. However, no significant correlation was found
- 32 between midlife blood pressure control, late-life visit-to-visit DBPV, visit-to-visit pulse pressure (PP) variability,
- and cognitive scores. These results suggest that late-life blood pressure control and variability may have a
- 34 more significant impact on cognitive function than midlife blood pressure.<sup>21</sup> The findings are in agreement with
- 35 the results reported by Rouch et al. And Dregan et al.<sup>14, 25</sup>
- 36 Yano et al showed that higher midlife SBP levels were associated with lower cognitive function in later life.<sup>18</sup>
- 37 Consistent research findings indicate that individuals with higher SBP levels during midlife tend to experience
- 38 lower cognitive function as they age. These studies have consistently demonstrated an association between
- 39 elevated SBP in middle age and subsequent cognitive impairment or impairment in later life. The link between
- 40 midlife SBP and cognitive function suggests that maintaining optimal blood pressure levels during midlife may

- 1 play a crucial role in preserving cognitive abilities and reducing the risk of cognitive impairment as individuals
- 2 grow older.<sup>26-28</sup> This suggests that elevated blood pressure during midlife may have long-term implications for
- 3 cognitive health.

#### 4 Association of Blood pressure variability with Dementia and cognitive impairment

- 5 Elevated SBPV and DBPV independently associated with a higher risk of dementia and cognitive impairment,
- 6 surpassing the impact of mean blood pressure.<sup>3</sup> Chiu et al observed insignificant results regarding the
- 7 incidence of cognitive impairment and no significant association between all-cause dementia risk and SBP.<sup>20</sup>
- 8 In contrast, Ma et al. indicated that a large variation in both SBP and diastolic blood pressure (DBP) was
- 9 associated with an increased risk of dementia.<sup>7</sup> This association became more pronounced with longer
- 10 intervals between the assessment of blood pressure variation and the diagnosis of dementia. Similarly, Yoo et
- al focused on the relationship between hypertension and the risk of all-cause dementia, AD, and VaD. The
- 12 findings demonstrated that hypertension increased the risk of all-cause dementia, AD, and VaD. Furthermore,
- 13 there was an incrementally higher risk of these outcomes with SBPV and DBPV.<sup>8</sup>
- 14 Rouch et al. examined the association between blood pressure variability and cognition and found that higher
- 15 systolic and DBPV were independently associated with poorer cognition, even when controlling for baseline
- 16 SBP and DBP, respectively. In line with previous research, this study found that while SBPV was associated
- 17 with poorer cognitive performance and an increased risk of developing dementia, the strongest associations
- 18 were observed for DBP and mean arterial pressure (MAP).<sup>17,22,23,29-31</sup> This suggests that blood pressure
- 19 variability, regardless of baseline blood pressure levels, may contribute to cognitive impairment.

#### 20 Effects of Anti-hypertensives on Dementia and cognitive impairment

- 21 Hughes et al performed a meta-analysis and demonstrated that blood pressure lowering with anti-
- 22 hypertensive agents compared to control was significantly associated with a reduction in dementia or
- 23 cognitive impairment.<sup>4</sup> Additionally, they found a significant association between blood pressure lowering and
- 24 a reduction in cognitive impairment. However, no significant correlation was observed between blood pressure
- lowering and the standardized mean cognitive score.<sup>4</sup> These findings suggest that anti-hypertensive treatment
- 26 may benefit dementia and cognitive impairment, but it may not directly affect overall cognitive performance.
- 27 Similarly, Wijsman et al's trial focused on the association between blood pressure-lowering medication
- 28 (BPLM) and cognitive function/decline. Interestingly, they found no significant association between BPLM and
- 29 cognitive function or decline, despite investigating different combinations of blood pressure-lowering
- 30 medication.<sup>5</sup> This suggests that the specific medications used for blood pressure control may not have a direct
- impact on cognitive outcomes. Prince et al compared the effects of different treatments (diuretics, beta-
- 32 blockers, and placebo) on cognitive function. The study found no significant difference in the mean learning
- test coefficients and trail-making coefficients between the three treatment groups.<sup>16</sup> These results suggest that
- the specific type of anti-hypertensive medication may not significantly impact cognitive function.
- 35

### 36 **Prognostic value of SBPV or DBPV for cognitive impairment**

- 37 The prognostic value of BPV with cognitive impairment and dementia has been a subject of interest in various
- 38 studies. Several researchers have explored the association between BPV and cognitive outcomes, shedding
- 39 light on its potential as an independent predictor and its implications for dementia prevention.

- 1 Yoo et al. conducted a study emphasizing that BPV is an independent predictor for developing dementia and
- 2 its subtypes.<sup>8</sup> Their findings suggest that reducing BPV could be a target for preventing dementia in the
- 3 general population. Recent research has demonstrated a correlation between the occurrence of dementia and
- 4 elevated day-to-day or visit-to-visit BPV, as measured by the CV index.<sup>28,31</sup> This highlights the importance of
- 5 considering BPV as a potential risk factor and the need to control blood pressure fluctuations to mitigate
- 6 cognitive impairment. Chiu et al examined the association between SBPV and dementia risk and revealed that
- 7 higher SBPV was significantly associated with an increased risk of all-cause dementia.<sup>20</sup> The significant
- 8 association between higher SBPV and increased risk of all-cause dementia underscores the potential
- 9 prognostic significance of SBPV as a predictor for dementia development.
- 10 Böhm et al conducted a study focusing on the long-term effects of SBP variations and mean heart rate (HR)
- 11 levels on cognitive function in high-risk patients and demonstrated that these fluctuations were associated
- 12 with the development of cognitive impairment, decline, and deterioration in these individuals.<sup>6</sup> These findings
- highlight the prognostic significance of long-term SBP variations and mean HR levels as potential indicators
- 14 for identifying high-risk patients prone to cognitive impairment and decline.<sup>22</sup> In contrast, one study revealed
- 15 the prognostic significance of excessive BPV for the progression of cognitive impairment.<sup>32</sup>
- 16 Collectively, these studies contribute to our understanding of the prognostic value of BPV for cognitive
- 17 impairment. While there is evidence suggesting that BPV is an independent predictor of dementia and its
- 18 subtypes, further research is needed to elucidate the specific associations and underlying mechanisms.
- 19 Reducing BPV and maintaining stable blood pressure levels may hold promise as potential preventive
- 20 strategies for cognitive impairment and dementia. Continued investigation into the role of BPV in cognitive
- 21 health will be crucial for developing targeted interventions and improving overall cognitive outcomes.

#### 22 STRENGTHS

- 23 The systematic review has notable strengths that enhance the reliability and comprehensiveness of our
- findings. By including studies with different durations of blood pressure follow-up, we could better understand
- 25 how blood pressure affects cognitive performance over time. These studies ranged from a few months to
- several years, allowing us to examine short-term and long-term effects. As a result, our review offers
- 27 significant insights into how blood pressure fluctuations may impact cognitive abilities.
- 28

#### 29 LIMITATIONS

- 30 The main limitation of our review is the differences in diagnostic criteria, cognitive assessment tools, and
- imaging techniques employed across the studies that may contribute to variations in the reported results.
- 32 These discrepancies may have contributed to heterogeneity in the reported results and limited the ability to
- make direct comparisons and draw generalizable conclusions. The use of different diagnostic criteria for
- 34 dementia introduces variability in case identification and classification, potentially impacting the synthesis of
- findings. Additionally, the inclusion of specific populations, such as older adults or individuals with
- 36 cardiovascular diseases, may restrict the generalizability of the observed associations between blood
- 37 pressure variability and cognitive outcomes. Furthermore, despite our comprehensive search strategies to
- 38 minimize publication bias, its potential influence on the results cannot be completely ruled out.
- 39

#### 1 CONCLUSION

- 2 In conclusion, the systematic review explored the effects of BPV and its association with dementia and
- 3 cognitive impairment. After an in-depth analysis, we were able to derive significant findings. In addition to
- 4 using cognitive tests like the MMSE, Digit Symbol Substitution Test, and the Word Recall Test to assess
- 5 cognitive changes, we also measure the diagnosis of dementia in the patient set.
- 6 Firstly, the studies indicate a high risk in the elderly subgroup, a stronger association of late-life blood
- 7 pressure with cognitive impairment, and long-term implications of midlife blood pressure. Secondly, we
- 8 emphasize the association between blood pressure variability and poor cognition suggesting the need for
- 9 early intervention and continuous monitoring of blood pressure fluctuations. We share the impact of anti-
- 10 hypertensive treatment on cognitive performance. Lastly, we cover the potential of using BPV as a predictor
- 11 for dementia and its implications for preventing cognitive impairment.
- 12 In terms of future research recommendations, we propose investigating the specific mechanisms underlying
- 13 this relationship to better understand the pathophysiology and develop targeted interventions. Conducting
- 14 longitudinal studies to establish a causal relationship between BPV and cognitive impairment and exploring
- the potential moderating factors, such as age, gender, and comorbidities, could provide a more
- 16 comprehensive understanding of the relationship. Implementing strategies to reduce BPV may help mitigate
- the risk and improve cognitive outcomes in susceptible populations. By emphasizing the need for further
- 18 research and highlighting potential interventions, we hope to provide valuable insights for healthcare
- 19 professionals, policymakers, and individuals seeking to maintain cognitive health.

#### **SUMMARY - ACCELERATING TRANSLATION** 1

2 Introduction: Dementia's global prevalence is surging, affecting about 50 million people, with projections 3 indicating a threefold increase by 2050. Beyond the significant public health impact, the economic burden is 4 substantial, with annual global costs estimated at \$1 trillion. Hypertension, once primarily linked to vascular 5 dementia, is now associated with Alzheimer's disease. Midlife hypertension is identified as a modifiable risk 6 factor for late-life dementia. However, the precise mechanisms connecting hypertension, blood pressure variability (BPV), and cognitive impairment leading to dementia remain unclear. 7 8 9 Aim of Study: This systematic review aims to investigate the correlation between high blood pressure, BPV, 10 and cognitive impairment, along with exploring the potential preventive role of anti-hypertensives. Key questions include the age and gender composition of study participants, the impact of BPV on dementia risk, 11 12 diagnostic methods used, and the effects of anti-hypertensive medications. 13 Methodology: Following the PRISMA 2020 guidelines, a thorough literature search identified 12 relevant 14 15 studies from sources like PubMed, Research Gate, Google Scholar, and ScienceDirect. Inclusion criteria 16 focused on English language studies, human participants over 50 years, and a clear investigation into the 17 association between BPV and dementia. After screening, 17 studies, involving 16,985,492 participants, were 18 included in the review.

19

20 Results: Midlife hypertension consistently showed an increased risk of cognitive disorders. The duration of

21 blood pressure follow-up and mean blood pressure values varied across studies, providing insights into the

22 relationship between blood pressure and cognitive outcomes. Elevated SBPV and DBPV were independently

23 linked to a higher risk of dementia and cognitive impairment, surpassing the impact of mean blood pressure.

24 Anti-hypertensive medications were associated with a reduction in dementia risk, although the impact on

25 overall cognitive performance was inconclusive. Different types of medications did not show significant

26 differences in cognitive function outcomes. Studies highlighted the prognostic significance of BPV for cognitive

27 impairment. Elevated day-to-day or visit-to-visit BPV was identified as an independent predictor for developing

28 dementia, emphasizing the need to control blood pressure fluctuations. Long-term SBP variations and mean

29 heart rate levels were associated with cognitive decline, indicating their potential as indicators for identifying

high-risk patients prone to cognitive impairment. 30

31

32 Conclusion: In summary, the intricate connection between high blood pressure, BPV, and cognitive

33 impairment leading to dementia is a global health challenge. Evidence suggests that midlife hypertension

34 poses a significant risk, and controlling blood pressure in later life may help reduce the likelihood of cognitive

35 decline. Anti-hypertensive medications show promise in lowering dementia risk, but their impact on overall

- cognitive function requires further investigation. 36
- 37

38 The findings reveals the importance of managing blood pressure variability, maintaining stable blood pressure

39 levels, and considering personalized interventions for individuals at risk. This research provides valuable

40 insights into the global concern of dementia, laying the groundwork for targeted preventive strategies and

- 1 improved cognitive outcomes. Continued research in this field is crucial to unravel the specific mechanisms
- 2 and optimize interventions for a healthier aging population worldwide.
