Determinants of Residency Program Choice in Two Central African Countries: An Internet Survey of Senior Medical Students

Ulrick S. Kanmounye,1 Mazou Temgoua,2 Francky T. Endomba,3

Abstract
Background: Central African countries have an increasing burden of disease, low specialist workforce densities, and under-resourced postgraduate medical education. The residency program choice of today’s medical students will determine specialist workforce density in the near future. This study aims to elucidate the factors that influence the choice of residency programs among medical students of two Central African countries. Methods: We designed an online questionnaire in French and English with closed-ended, open-ended, and Likert scale questions. Links to both forms were shared via the international messaging application, WhatsApp, and data were collected anonymously for one month. Respondents were sixth- and seventh-year medical students enrolled in nine Cameroonian and Congolese schools. The threshold of significance was set at 0.05 for bivariate analysis. Results: There were 149 respondents in our study, 51.7% were female, and 79.2% were from Cameroon. Almost every student (98%) expressed the wish to specialize, and a majority (77.2%) reported an interest in a residency program abroad. Preferred destinations were France (13.7%), Canada (13.2%), and the U.S.A. (11.9%). The most popular specialties were cardiology (9.4%), pediatrics (9.4%) and obstetrics and gynecology (8.7%). The choice of specialty was made based on the respondent’s perceived skills (85.9%), anticipated pay after residency (79.2%), and patient contact (79.2%). Conclusion: Understanding which specialties interest Cameroonian and Congolese medical students and the reasons for these choices can help develop better local programs.

Key Words: Career choice; Internship and residency; Surveys and questionnaires; Cameroon; Democratic Republic of the Congo (Source: MeSH-NLM).

Introduction
Cameroon and Democratic Republic of Congo (DRC) are Central African countries with high burdens of infectious and maternal diseases, low health investments, and high incidences of catastrophic health expenditure due to a lack of universal health coverage.1,2 The overburdened Cameroonian and Congolese health systems are stressed further by conflicts and disasters.3,4 Limited medical school admissions and local residency positions are pushing medical graduates to educational migration. Also, a considerable percentage of African medical graduates tend to go abroad because foreign programs are perceived to be of higher quality.5,6 This decreases the physician workforce density and limits patient access to specialist care in African countries. Specialist care plays a significant role in the healthcare system as it leads to prompt diagnosis, adapted care, and generally better outcomes for patients.7 Postgraduate medical education (PGME) programs should equip their graduates with the skills to tackle the nation’s public health challenges. Understanding the determinants of residency program choice can offer more chances to reach the disparities in certain specialties. For example, women are poorly represented in some specialties8-10 despite making up more than half of the medical student body.11,12 This disparity is accentuated in African society, where women tend to be less interested in specialties that are viewed as “demanding.”13,14

Cameroon has 1,420 general practitioners and 422 specialists serving 25 million inhabitants.15 Admission into the 7-year medical school programs is through a unique national examination for undergraduates, and successful candidates get into one of 8 medical schools (six public and two private). The first three years are pre-clinical, the next three are clinical, and the last year is reserved for the thesis. At the end of the sixth year, students take a national examination (Examen National de Synthèse Clinique et Thérapeutique) made of a written and a practical section. Successful candidates can apply for an academic specialty program known as internat, and if selected, they then go on to start their specialty the following year. Those who are not interested in internat and those who failed to get into internat can apply for another specialty program known as résidant once they have totaled at least two years of general practice.

The DRC, on the contrary, has 84 million inhabitants and 4,500 (2,000 specialists and 2,500 general practitioners) of the country’s 25,000 physicians that practice in the capital city. The number of medical schools has grown exponentially.16 From 19 nationwide in 2010, there are now 25 in the capital city (Kinshasa) alone.17 Training in the DRC is divided into three pre-clinical years called graduat and four clinical years called doctorat. The last year of doctorat, quatrième doctorat, is spent doing rotations for a period between 14 to 18 months divided into at least: 1-month neurology, 1-month psychiatry, 4-month medicine, 4-month surgery, 4-month obstetrics and gynecology, and 4-month pediatrics rotations. Medical graduates can apply for residency if they pass the admissions tests organized by each program.

Cameroonian and Congolese medical graduates are considered fit to practice as soon as they get licensure from their respective national medical bodies. The state is the major employer in both countries and the state’s budget limits recruitment.18 There are no rural practice
Determinants of Residency Program Choice in Two Central African Countries: An Internet Survey of Senior Medical Students

Kanmounye US, et al.

Materials and Methods

Study Design and Participants

We conducted a descriptive cross-sectional study, and our target population was defined as sixth- and seventh-year students enrolled in Cameroonian and Congolese medical schools. We distributed our survey to a teaching hospital. Little is known about how Cameroonian or Congolese medical students choose their residency programs. We aimed to identify the determinants of residency program choice among senior medical students in Cameroon and the DRC.

Materials and Methods

Study Design and Participants

We conducted a descriptive cross-sectional study, and our target population was defined as sixth- and seventh-year students enrolled in Cameroonian and Congolese medical schools. We distributed our survey to a teaching hospital. Little is known about how Cameroonian or Congolese medical students choose their residency programs. We aimed to identify the determinants of residency program choice among senior medical students in Cameroon and the DRC.

Questionnaire

The questionnaire comprised five sections: the first section included sociodemographic data (gender, age, marital status, medical school, medical schools’ private/public status, year of study). The second section covered the students’ preferred residency programs and the reasons for choosing these programs. The questionnaire evaluated the importance of each determinant, while surgical specialties were the most commonly recommended (64.4%, n=133), followed by general medicine (51.7%, n=133) and pediatric (12.8%, n=133). Sixty-four students (43.0%, n=149) followed the advice given to them (Table 1).

When asked what they would choose between their least favorite specialty abroad and their favorite specialty at home, 104 (69.8%, 95% CI: 61.7%-77.3%) chose their favorite specialty. 77 (51.7%) students agreed they would accept a residency offer if it entailed having to practice in a rural area at the end of residency while 46 (30.9%) were hesitant. Students that hesitated or refused to accept such an offer reported they might change their minds if rural outposts were better equipped (10.5%, n=18) or if they were given financial incentives (4.0%).

Participants from this study chose Africa (30.2%) as the second most popular continent for residency program choice behind Europe (38.2%). The most popular countries for residency training were France (15.7%), Canada (11.2%), and the U.S.A. (11.2%) (Figure 1). The main reason for wanting to train abroad was to get better training (68.5%). Additionally, 6.7% of students wished to train abroad because they felt foreign programs were more prestigious, while 3.4% wished to train abroad because their preferred specialty was not available for PGME in their home country. Some interesting quotes by our respondents:

"We lack doctors in my preferred specialty in my country, and I wish to improve the health of my countrymen."

"My country needs me more, plus we were trained to take care of the sick and needy. Patients exist everywhere, so [physicians] should equally exist everywhere."

Most participants (58.4%, 95% CI: 50%-66.4%) had previously changed their minds on their specialty choice. 133 (89.3%, 95% CI: 83.1%-93.7%) respondents reported that they had been advised to take up a specialty. These students had been encouraged by a family member (64.4%, n=133), a friend (30.2%, n=133), or a teacher (21.5%, n=133) to choose a specialty over another. The most commonly recommended specialties were obstetrics and gynecology (25.2%, n=133) and pediatrics (12.8%, n=133). Sixty-four students (43.0%, n=149) followed the advice given to them (Table 1).

Data was exported from Google Forms to Excel (Microsoft Corp, WA, U.S.A.), coded and analyzed using SPSS v24 (Statistical Package for the Social Sciences, SPSS Inc, U.S.A.). 95% confidence intervals, bivariate, and multinomial regression analyses were run. The alpha value was set at 0.05. The Likert responses were organized into three categories: strongly disagree and disagree, undecided, and agree and strongly agree. Agree and strongly agree were the reference for the level of importance of each determinant, while surgical specialties were the reference category for PGMEs. The visualizations were generated using Tableau Public v2019.4.1 (Mountain View, CA, U.S.A.).

Results

Of the 186 eligible final year medical students approached in Cameroon and the DRC, 149 respondents (response rate: 80.11%) consented to the study, and the same number completed the survey. There were no incomplete surveys, and we were unable to distinguish abandonments from non-response. Following data cleaning and analysis, we did not find ineligible respondents among our sample. The mean age was 25.29 years ± 1.97. 52% of participants were female, 86.6% were single, 79.2% went to school in Cameroon, 56.4% were in public schools, and 75.8% were in their seventh year of medical school. Almost every participant (98%) expressed a firm desire to get into residency, 114 respondents (72.2%) intended to do their residency abroad, and 114 (76.5%) reported that they would come back home after their training abroad. Those who wished to return after their residency training stated the need to help the vulnerable (40.3%) and the need to serve the state (36.9%). Some answers from our respondents are below:

"We lack doctors in my preferred specialty in my country, and I wish to improve the health of my countrymen."

"My country needs me more, plus we were trained to take care of the sick and needy. Patients exist everywhere, so [physicians] should equally exist everywhere."

Most participants (58.4%, 95% CI: 50%-66.4%) had previously changed their minds on their specialty choice. 133 (89.3%, 95% CI: 83.1%-93.7%) respondents reported that they had been advised to take up a specialty. These students had been encouraged by a family member (64.4%, n=133), a friend (30.2%, n=133), or a teacher (21.5%, n=133) to choose a specialty over another. Participants from this study chose Africa (30.2%) as the second most popular continent for residency program choice behind Europe (38.2%). The most popular countries for residency training were France (15.7%), Canada (11.2%), and the U.S.A. (11.2%) (Figure 1). The main reason for wanting to train abroad was to get better training (68.5%). Additionally, 6.7% of students wished to train abroad because they felt foreign programs were more prestigious, while 3.4% wished to train abroad because their preferred specialty was not available for PGME in their home country. Some interesting quotes by our respondents:

"I wish to train abroad because education and remuneration are better than at home. There are more opportunities to grow abroad, and I can directly access my specialty without having to wait to gain experience."
The most popular first choice specialties in our study were cardiology (14.9%), pediatrics (14.9%), and obstetrics and gynecology (18.7%). 24.7% of women chose a surgical specialty, while 14.3% chose pediatrics as their first choice. On the other hand, 44.4% of men chose surgical specialty, while 4.2% chose pediatrics as their first choice (Table 2).

The majority of study participants identified personal skills for the job (85.9%), patient contact (79.2%), and anticipated pay after residency (79.2%) as being essential to choosing a residency program (Figure 2). Only eight students (5.5%) estimated the specialist average monthly salary to be above USD $1,070, the median of the specialist monthly wage estimation was USD $982-1,070, and the mode was USD $1,607 (25.5%). 83 (55.7%) felt there was no factor other than the pre-identified 11 that influenced their residency choice. Other factors reported included passion for the specialty (8.1%), better opportunities for the specialty (6.0%), and family (3.4%). The main reason for not liking a specialty was a lack of interest (58.4%).

We found a statistically significant small to moderate association between male gender and having been discouraged from doing a particular specialty (Phi -0.213, p = 0.009). Enrollment at a public or private school (p=0.859), being discouraged (p=0.619), and being encouraged (p=1.000) by someone to do a particular specialty were not found to be associated with specialty choice. No association was found between the intent to specialize on the one hand and deciding on whether to practice in a rural area (p=1.000), being encouraged to do a specialty (p=0.113), and being discouraged from doing a specialty (p=0.015). The choice of specialty was significantly associated with perceived specialty prestige (p=0.04) and previous experience (p=0.05). Multinomial analysis of the level of agreement on the importance of each factor is reported in Table 3. The importance of prestige (p=0.004) and strong disagreement/disagreement of the importance of previous experience (p=0.002) to specialty choice were both statistically significant among students who chose specialties that were neither medical nor surgical (Table 3).

Table 3. Cameroonian and Congolese Medical Students’ First Speciality Choice by Frequency and Percentage.

The majority of study participants identified personal skills for the job (85.9%), patient contact (79.2%), and anticipated pay after residency (79.2%) as being essential to choosing a residency program (Figure 2). Only eight students (5.5%) estimated the specialist average monthly salary to be above USD $1,070, the median of the specialist monthly wage estimation was USD $982-1,070, and the mode was USD $1,607 (25.5%). 83 (55.7%) felt there was no factor other than the pre-identified 11 that influenced their residency choice. Table 3. Cameroonian and Congolese Medical Students’ First Speciality Choice by Frequency and Percentage.
**Discussion**

Cameroonian and Congolese students, like their Kenyan colleagues, wish to get into residency.\(^1\) PGME fosters learning and mastery of a medical specialty in a formal setting and affords physicians career opportunities, higher social standing, and better remuneration. Cameroonian general practitioners in the public sector earn between USD $262 - $292 on average per month as opposed to the highest Cameroonian specialist earners, surgeons, who earn up to USD $1,491 per month on average.\(^2\) Medical students estimated specialists earned an average monthly salary of USD $1,607, well above the USD $300 – $600 monthly income of the African middle-class, and they felt remuneration after residency was critical when choosing their future specialty.\(^3\)

Cameroonian and Congolese students rotate through surgery, obstetrics and gynecology, pediatrics, and internal medicine. During this period, they develop skills, and they get to build bonds with patients in these departments. They equally experience the challenges of medical practice and PGME training in-country. PGME in developing countries is faced with a lack of financial resources, a dearth of qualified medical educators, and these impact the quality of PGME training. Few local residency programs can compete with the resources and prestige of foreign programs. While residency programs of developed nations have successfully integrated innovative solutions to their PGME, residency programs in low-resource settings, often lack residency spots and the infrastructure necessary for quality PGME training. Local programs must develop novel, sustainable, and low-cost solutions in order to improve the quality of their PGME and to garner the attention of their medical students. Some programs, like the College of Surgeons of East, Central and Southern Africa, and the West African College of Surgeons, have successfully developed training models that make use of foreign and local resources. This combination has led to an increase in the number of trained specialists and high retention of graduates on the African continent.

Admission to foreign residency programs is extremely competitive and costly. African countries lose financial and human resources to Western countries as those willing to study in world-renowned institutions migrate. Having quality local PGME programs can reduce brain drain from medical workforce migration and reduce capital flight. Similarly to our survey participants, 88.2% of medical students in Malawi, and 65% of medical students in Botswana intend to train abroad.

In contrast, South African medical students prefer to study in their home country. South Africa, unlike most sub-Saharan African countries, is advanced economically and scientifically. Its medical education is reputed for its quality medical education and research. This might explain why less South Africans are willing to go abroad for their specialization while most Cameroonians and Congolese wish to go to more developed countries like South Africa for their PGME. This difference is corroborated by the fact that most survey respondents chose to train in their favorite specialty at home instead of training in their least favorite specialty abroad.

Although most medical students intend to migrate, they are equally willing to return home once they complete their training. Return to practice in a low-resource setting can be a daunting task for a physician who has become accustomed to working in the Western world. Often newly graduated specialists return home to hospitals that lack equipment and often have to build a service from the ground up. If a residency program is not available in-country, training in an African country offers an environment similar to the home country. It is encouraging that a considerable number of students chose African countries as their destination for PGME training.

Specialties that offer medical students with greater exposure to patients tend to elicit a greater sense of confidence. The confidence that medical students have in their clinical ability increases with supervision, and transition from the lab to the bedside. Both previous exposure to future specialty and perceived skill were essential factors in the choice of future medical specialty to our participants. Similarly, Brazilian medical students emphasize previous experience, perceived skill, and patient contact. Remuneration is equally vital in the choice of a specialty. Although American military medical students choose their specialty based on interest when compensated reasonably, they are more likely to choose less-desirable specialties. We posit that the choice by our respondents of pay after residency can be attributed to the fact that medical training is costly, lengthy and demanding. Medical school tuition cost can amount to USD $2,279 in some Cameroonian and Congolese private schools, and training lasts at least seven years in both countries. In the DRC, it is not uncommon for medical students to graduate with a delay of up to 18 months. This delay, année élastique (elastic year), often occurs during the seventh academic year. This is a stressful period for students given that they do not have a medical license, they cannot take up remunerated jobs and therefore depend on their parents for financial assistance. This in part explains the strong desire to train abroad where there are less uncertainties.

Sub-Saharan Africa has the lowest regional medical workforce despite having the highest burden of disease in the world. We must pay attention to those specialties that have a high burden of disease to workforce ratio through strategies aimed at those who are least interested or least represented. Local governments should partner with their medical diaspora and foreign partners to develop residency programs and opportunities for medical students. The medical diaspora and foreign medical bodies have the skills, resources, and experience to help bring these plans to fruition, but it is up to local governments to develop policies that incentivize their participation.

Limitations to the study include the small sample size and low representation of Congolese medical students. The low representation might be due to the expensive cost of broadband, USD $1 buys between 130-165 Mb of broadband in the DRC, and most students cannot afford the internet daily. Second, by choosing a cross-sectional study design, we could only establish correlation and not causation. The fact that 58.4% of respondents reported having changed their mind before on their specialty choice suggests that some might change their minds in the future. Ideally, we should have followed our participants from medical school to their admission into residency to establish if they had changed their minds. However, this was not possible due to a lack of resources. Next, surveys are prone to a multitude of biases, which can complicate their interpretation. We minimized social response bias by guaranteeing anonymity to our respondents and addressed non-response bias and self-selection bias by sharing our survey by text and WhatsApp while sending reminders every ten days. Despite these limitations, we believe our findings give an insight into some of the motivations of Cameroonian and Congolese medical students who wish to get into a residency program. Future studies should focus on whether these future African medical doctors get into the residency program of their choice, whether they succeed in migrating to the country of their choice and whether they return once they have been trained abroad. Such studies can inform the decision-makers as they design PGME programs.

Medical students from Cameroon and the Democratic Republic of Congo are eager to get into a specialty. They wish to have the best PGME and are willing to travel for this purpose. Their preferred destinations for training are France, Canada, and the United States. Cardiology, pediatrics, and obstetrics and gynecology are the most popular specialties, and their choice is influenced by skills, patient contact, and remuneration after residency. Local program directors must evaluate the quality of programs currently available and modify them to meet the expectations of medical students.
